Abstract

Phytoremedies are becoming mainstream worldwide; the increasing of these medicinal approaches is due to the recognition of the value of traditional medicine and indigenous pharmacopoeia. Although medicinal plants are often promoted as natural and therefore harmless, they are not free from adverse effects. The potential toxicity of herbal medicine is not new. In several countries, where herbal medicines are commonly used, it is well known that some plants must be used with caution because the adverse reaction can be caused inherently by toxic herbs, by herbs overdoses, or by drug-drug interaction, thus, especially other adverse reaction can be due to quality problems such as adulteration caused by manufacturing, misidentification, substitution of one herbs for another, improper processing of preparation and use, etc...

The present study reviews the cases of some plants commonly used by Moroccan people in traditional medicine and reported as highly toxic. Twenty eight plants are selected dangerous for health; these toxic species belonging to 16 families have been repertoried. The families reported to be most representative of these kinds of plants are Solanaceae (7 species). All physiological functions can be affected by the toxicity of plants. However, the highly toxic plants reviewed are those which produce irreversible health injury, serious aftermath, and irreversible damage such as renal failure, liver damage, hemiplegia, blindness...etc and sometimes they can produce the death. The plants that have been reported to produce the sever damages are: *Aconitum vulparia* Rchb., *Anagyris foetida* L., *Atractylis gummifera* L., *Bryonia dioica* Jacq., *Chenopodium album* L., *Colchicum autumnale* L., *Conium maculatum* L., *Daphne gnidium* L., *Daphne laureola* L., *Ferula communis* L., *Hyoscyamus niger* L., *Mandragora autumnalis* Bertol., *Nerium oleander* L., *Ricinus communis* L., *Solanum nigrum* L., *Tamus communis* L. and *Thapsia garganica* L.

The review indicates the scientific name of the plant (family and specie), the vernacular name, the part used, the LD50 (lethal dose 50) and summarized the most relevant toxicological investigations. The products carrying the toxicity of the plants and the acute toxicity have been mentioned. The great part of these toxic drugs belongs to the alkaloid class.

Key words: Toxic plants, Active components, Toxicity, Traditional medicine.

Introduction

The use of herbal medicines has increased considerably over the last decade over the world. Widespread reliance on traditional medicine can attributed to 1) High cost of conventional medicine; 2) The belief that

herbal remedies are innocuous in contrast to conventional drugs; 3) The idea that what is natural can only be good; 4) The development of new diseases with severe complications, for which there is still no appropriate treatment and 5) The belief that herbal medicines are natural and safe.

Although phytotherapy continues to be a main strategy of remedies in several countries, few plants received scientific or medical scrutiny (Gray and Flatt, 1998). Moreover, a high number of the medicinal plants possess a degree of toxicity. For example, it was reported that about one third of medicinal plants used in the treatment of diabetes are considered to be toxic (Marles and Fransworth, 1988).

This review is based on the literature such as using Medline and other reference sources materials including the books, the Moroccan thesis, the papers and reviews published in scientific journals and websites (such as FDA database and Cornell Poisonous plants) giving database on ethnobotanic, phytotherapy and toxicology. The Medline search included the following key words: herbs, herbal, traditional medicines, phytoremedies, toxicity, adverse effects, adverse reaction, drug-drug herbs interaction, overdose. In order to clarify this field for the scientific researchers as well as for the herbalists and users, we focused our searches only on the highly toxic plants commonly used by Moroccan people in traditional medicine in order to better highlight this field and to provide guideline for plant medicines users as for the herbalists, practitioners and consumers.

In this view we listed twenty seven plants more dangerous if they don't used carefully. These plants are those which produce irreversible health injury, serious aftermath, and irreversible damage such as renal failure, liver damage, hemiplegia, blindness...etc and sometimes they can produce the death.

Indeed, the list is best used only as a preliminary screening of potentially poisonous plants, not as a definitive conclusion of toxicity and a complete list of toxic plants.

Discussion

Several toxic plants (used with adequate amounts in traditional medicine) were useful for humanity during many centuries for the treatment of certain serious illnesses.

The colchicine, which is a highly toxic drug, obtained from *Colchicum autumnale* was very useful against congestive heart failure. The digitalin obtained from digital known for its high toxicity was very useful for the treatment of cardiac insufficiencies. In the same way we know very well the diverse important medical applications of the narcotics obtained from very toxic plants. These sorts of applications concern for example the belladonna that has a remarkable importance in pharmaceutical industry. Indeed, it intervenes in the manufacture of 86 drugs; that is to say, 10.42 % of pharmaceutical product in Morocco (Choulli et al. 1999). Although the seeds of *Citrullus colocynthis* are highly toxic, they were used for the treatment of diabetes. Recently, it has been shown that this plant contains insulinotropic compound (Abdel-Hassan et al. 2000. Nmila et al. 2000). The toxicity (acute toxicity) of some of these plants was largely highlighted. In Morocco, it was noted that a great number of intoxication cases in the Moroccan Poison Center (CAPM) are due to ingestion of the plants and products of traditional pharmacopoeia (2.5 % of the declared cases of intoxications) (CAPM). The most fatal toxic products in Morocco are the plants and the products of the traditional pharmacopoeia whose lethality reached 17 %. CAPM has registered 100 cases of intoxication by *Atractylis gummifera* between 1992 and 2000; that is to say 87.7 % of the total number of the registered cases (CAPM).

Since intoxications by *Atractylis gummifera* L. frequently happens in Morocco, this plant was relatively well studied in Morocco. Several tens of case of accidents due to the intoxication by *Atractylis gummifera* were studied and published (Berrada 1979, Sandali 1970). These studies made it possible to draw a clinical table related to the ingestion of *Atractylis gummifera*. This table includes a phase of latency of 24 H to 48 H before the appearance of the first signs of the intoxication. There is initially appearance of the digestive disorders then respiratory, cardiovascular disorders, and hepato-renal function disorders.

Table 1. Presentation of some plants used in Moroccan traditional medicine, their scientific names, the family, the vernacular name, the used parts, and information about medicinal uses, toxic components and toxicological signs

Scientific names Species names Family names	Local vernacular names	Used part	Medicinal uses	Toxics compounds	Toxicological signs	DL50 (mg/kg)	References
<i>Aconitum vulparia</i> Ranunculaceae	- Igantar or Ijantar - Quatel ed-dib - Hanq ed-dib	Root	Analgesic; Antirheumatic; Anticongestif; Against sciatic and teeth pain	- Aconitine	Vertigo; Diarrhea; Hypertension; Shivering Tachycardia; Respiratory paralysis	Iv cat 0,07-0,13 Iv rat 0,08-0,14 Or rat 1 Iv mouse 0,12 Sc mouse 0,27 Ip mouse 0,38 Or mouse 1,8	9,12,19

World Health Organization Expert Committee on Diabetes Mellitus; 1980; 37. Ziyyat et al., 1997

Finally a hepatic coma and death occurs 4 to 6 days after ingestion of *Atractylis*. In order to take stock of this intoxication of which diagnosis is clinical and treatment symptomatic, Skalli et al. in 2000 have suggested analyzing one clinical case of the intoxication by *Atractylis gummifera* L. on a 12 year old child who accidentally ingested this plant. In fact, the sweetened taste of the root of this plant especially facilitates the intoxication in the child (Bellakhdar, 1997).

The intoxication by seeds of *Ricinus communis* can be accidental. The seeds of the fruits of *Ricinus communis* are frequently confused with edible seeds. The intoxication can occur by therapeutic overdose or following their use as abortive. Bellakhdar in 1997 reported that intoxication has been produced in Goulimine (southern of Morocco) following a traditional treatment against female sterility consisting of the *Ricinus communis* seed ingestion associated with a vaginal rectal injection with a solute of seed decoction. The castor seeds are often used like abortive (Bellakhdar, 1997).

The intoxications by another toxic plant: *Ferula communis* are well known in Morocco as well for the animals as for the Man. It is a plant which was much studied. The toxic principle of this plant is concentrated in secretions which give a product locally called "Fessoukh". This product is not water soluble and hexane but it is soluble in the acetone, the chloroform and solution of NaOH (3 %) (El Alouani, 1986). It has been tried to profit to prepare rodenticide from *Ferula communis*

(Abadome, 1988). Moreover, a trial conducted with wild rats using 0.1 % "Fessoukh" extract baits demonstrated "Fessoukh" rodenticide effects (Fraigui et al. 2001).

The most toxic plants listed in this review are 28 species belonging to 16 families. The familie that have been reported to be most representative of the highly toxic plants used in the traditional medicine in Morocco is Solanaceae (7 species).

A great part of the poisonous substances of the plants listed in this review belongs to the class of alkaloids. It is the case of the following plants: *Aconitum vulparia*, *Anagysis foetida*, *Atropa belladonna*, *Conium maculatum*, *Datura stramonium*, *Digitalis purpurea*, *Hyoscyamus niger*, *Mandragora autumnalis*, *Withania somnifera*.

In conclusion, the families most representative of these plants are the family of Solanaceae (7 species). The intoxication by these plants is not only related to the fact that they are used in traditional herbal medicine but more especially because of some factors such as: the overdose, bad methods of use as well as confusion with other edible plants. The children are touched the most by these intoxications. The majority class of the toxic principles of these plants belongs to alkaloids. Moreover, strong efforts are wished to inform populations that continue to use traditional medicine in order to avoid the bad practices due to the ignorance of the good uses of the traditional medicine.
